Abstract

Secret Sats lets you pay in bitcoin without revealing who paid whom, or how much. A self-custody lock on Bitcoin, backed by an Ethereum escrow, mints cBTC in Tacit's confidential pool, and zero-knowledge proofs, not signers, carry it back to Bitcoin as a native Tacit asset. There, every transfer hides its amount and pays a one-time, silent-payment-style address that only the recipient can find. Shielding cBTC into Tacit's Bitcoin pool also hides where a payment came from, and relayers post it so the sender needs no Bitcoin wallet. Sats enter and leave by atomic swap today, and by covenant the day Bitcoin allows one; the cBTC pilot is live on mainnet, and it all runs on signet.
